In re Patent Application of:  
Catherine Castan et al.

Application No.: 10/510,643

Confirmation No.: 1869

Filed: May 23, 2005

Art Unit: 1615

For: ORAL PHARMACEUTICAL FORMULATION      Examiner: C. E. Helm  
IN THE FORM OF AN AQUEOUS  
SUSPENSION OF MICROCAPSULES FOR  
THE MODIFIED RELEASE OF ACTIVE  
PRINCIPLE(S)

---

**DECLARATION OF CATHERINE CASTAN**

1. My name is Catherine CASTAN.
2. I have been an employee of Flamel Technologies, S.A. since 1992.
3. My position at Flamel Technologies S.A. is Director of R&D Oral Dosage

Forms.

4. I have a Ph.D. in Polymer Chemistry.
5. I have worked in the area of pharmaceutical compositions for 21 years.
6. I consider myself to be one of skill in the art of oral pharmaceutical compositions for modified release of active principles.
7. I reviewed the Office Action that issued on December 7, 2009, for U.S. Application No. 10/510,643.
8. I also reviewed U.S. Patent No. 4,902,513 ("Carvais") and U.S. Patent No. 6,022,562 ("Autant"), references cited by the Examiner in 35 U.S.C. § 103(a) rejections of Application No. 10/510,643.
9. In reviewing the Office Action, it is my understanding that the Examiner is alleging that it would have been obvious to one of ordinary skill in the art to employ coated particles of Autant et al. as the microcapsules in the sustained release, drug saturated suspension of Carvais. *See*, Office Action at page 9.

10. As one of skill in the art, I believe the claimed invention has unexpected and surprising properties because the claimed suspension of microcapsules in an aqueous liquid phase is found to confer the unexpectedly superior claimed release profile upon the microcapsules.

11. At the time of the application, one of ordinary skill in the art would have known that suspensions of microcapsules, including coated microcapsules, suffered from stability problems.

12. While this was known to those of skill in the art, further evidence of this is found in Santos et. al. (EP 0359195, page 2) from 1989 which stated that in the preparation of controlled release liquid pharmaceutical compositions, the "problem is the difficulty of obtaining controlled release liquid preparations apt to maintain for long times the release characteristics of the pharmaceutical substances contained.[...] It may explain why as far as we know, only few controlled release liquid systems are known up to now, and among them, only one is actually commercially available". In 2002, the stability of the release profile in controlled release liquid suspensions was still perceived as a problem difficult enough to explain limited commercial success. See excerpt from the reference textbook by Banks et al., "Modern pharmaceuticals, Volume 121", 4th Edition, Informa Health Care, pp. 396-8 (2002). See Appendix. Page 397 states: "The formulation of oral sustained-release suspensions has resulted in only limited success due to the difficulty in maintaining the stability of sustained release particles when present in liquid system." As such, it was unexpected for the coated microcapsules of the claimed invention to provide the beneficial stability characteristics as claimed. To the best of my knowledge, less than five controlled release liquid suspension products are commercially available today, indicating that the problem of stability is still current.

13. Page 397 of the Appendix to Banks et al. further states: "Formulation techniques, such as coated beads, drug impregnated wax matrix, microencapsulation, and ion exchange resin, have been used for this purpose". As such, it was unexpected for techniques intended to create sustained release particles, such as those listed on Page 397, to maintain a stability in liquid systems.

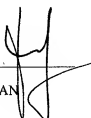

14. One of skill in the art would also expect that in a coated microcapsule where the coat contains water soluble materials, the soluble components would dissolve in water.

15. As such, it was unexpected that a microcapsule with a coating containing water soluble materials would maintain coating permeability when placed in an aqueous solution for 10 days.

16. Therefore, one of ordinary skill in the art at the time of the invention would not have foreseen that the claimed coating composition would produce a release profile in an aqueous liquid on day ten similar to the release profile on day zero.

17. Accordingly, Carvais in view of Autant could not teach the unexpected stability of the release profile as claimed: "wherein the *in vitro* release profile of the suspension of microcapsules in an aqueous liquid phase on day ten is similar to the release profile on day zero, as measured using a type II apparatus according to the European Pharmacopoeia 3rd edition, in a phosphate buffer medium of pH 6.8, at a temperature of 37°C".

18. I declare that all statements made of my own knowledge are true and all statements made on information and belief are believed to be true. I make this declaration with the understanding that willful false statements and the like are punishable by fine or imprisonment, or both (18 U.S.C. 1001) and may jeopardize the validity of the patent application.

Pharmaceuticals, Volume 121

**Abstract**

The recent five diffusion paths of the various antineoplastic and may thus protect the particle growth.

Polymerorphism refers to the different solid crystal structures of a chemically identical compound. Drugs may undergo a change from one polymorphic form to another polymorphic form to a more stable polymorphic form. Also, the crystal habit might change due to the degree of solution or hydration. The formation of dilute new crystallites occurs during storage is possible. For example, an aqueous solution of drug can be dried to a powder rapidly or slowly forms a dry cake. These various forms may exhibit different solubilities, melting points, and a hydrolytic pattern. In the preparation of suspensions using precipitation methods, the solvent and the rate of cooling are important factors determining the type of polycrystalline material.

Various drugs are known to exist in several polymorphic forms like, cinnamone and prednisolone. The rate of conversion from a metastable into the stable form is an important factor to be considered with respect to the shelf life of a pharmaceutical product. Polymorphic changes have also been observed during the manufacture of nasal suspension. When nasal powder are subjected to dry heat degradation, subsequent sublimation of substances results in the presence of an aqueous vehicle results in the formation of large, needle-like crystals. A similar effect may be produced by subject heated aspartame to assist their crystallization in an amorphous.

Lipids showed that crystal growth may also arise when the more energetic amorphous or glassy forms of a drug exhibit significantly greater initial solubility than their corresponding crystalline forms [84]. In addition, dry reduction by grinding and grinding can produce particles where different surface active layer or fast dissolution rates. This effect can be contrasted to differences in the free surface energy introduced during combination.

To prevent crystal growth and possible changes in particle size distribution, one or more of the following procedures and techniques may be employed (Table 1) selection of particles with a narrow size range (selection of a more stable crystalline form of drug) (avoidance of the use of high-energy milling during particle size reduction); incorporation of a wetting agent (e.g., mucic acid) results in a protective coating of the surface derivatives forming (like Van der Waals around the particles); (c) increase of the viscosity of the vehicle to retard particle dissolution and subsequent crystal growth; and (d) avoidance of temperature fluctuations during storage.

**Abstract**

**Introduction**

The recent five diffusion paths of the various antineoplastic and may thus protect the particle growth.

Polymerorphism refers to the different solid crystal structures of a chemically identical compound. Drugs may undergo a change from one polymorphic form to another polymorphic form to a more stable polymorphic form. Also, the crystal habit might change due to the degree of solution or hydration. The formation of dilute new crystallites occurs during storage is possible. For example, an aqueous solution of drug can be dried to a powder rapidly or slowly forms a dry cake. These various forms may exhibit different solubilities, melting points, and a hydrolytic pattern. In the preparation of suspensions using precipitation methods, the solvent and the rate of cooling are important factors determining the type of polycrystalline material.

Various drugs are known to exist in several polymorphic forms like, cinnamone and prednisolone. The rate of conversion from a metastable into the stable form is an important factor to be considered with respect to the shelf life of a pharmaceutical product. Polymorphic changes have also been observed during the manufacture of nasal suspension. When nasal powder are subjected to dry heat degradation, subsequent sublimation of substances results in the presence of an aqueous vehicle results in the formation of large, needle-like crystals. A similar effect may be produced by subject heated aspartame to assist their crystallization in an amorphous.

Lipids showed that crystal growth may also arise when the more energetic amorphous or glassy forms of a drug exhibit significantly greater initial solubility than their corresponding crystalline forms [84]. In addition, dry reduction by grinding and grinding can produce particles where different surface active layer or fast dissolution rates. This effect can be contrasted to differences in the free surface energy introduced during combination.

To prevent crystal growth and possible changes in particle size distribution, one or more of the following procedures and techniques may be employed (Table 1) selection of particles with a narrow size range (selection of a more stable crystalline form of drug) (avoidance of the use of high-energy milling during particle size reduction); incorporation of a wetting agent (e.g., mucic acid) results in a protective coating of the surface derivatives forming (like Van der Waals around the particles); (c) increase of the viscosity of the vehicle to retard particle dissolution and subsequent crystal growth; and (d) avoidance of temperature fluctuations during storage.

#### D. Pharmaceutical Suspensions

In the preparation of physically stable pharmaceutical suspensions, a number of formulation components can be incorporated to maintain the solid particles in the dispersed state. These substances can be classified as (a) components of the suspending system, including wetting agents, dispersants or deflocculating agents, flocculating agents, and thickeners, and (b) components of the suspending vehicle (external phase), including pH-control agents and buffers, osmotic agents, coloring/flavoring agents, preservatives, and liquid vehicles. The components of each category are individually selected for their use in the preparation of orally, topically, or parenterally administered suspensions.

# Dispersions 397

Orally administered suspensions containing a wide class of active ingredients (e.g. antibiotics, antacids, antispasmodics) are of major commercial importance. The solubility of an oral suspension may vary considerably. For example, antibiotic preparations may contain 125-500 mg solid drug per 5 ml, or a suspension dose, while a drug containing may provide the same amount of drug in only 1-2 ml. Antacid or antispasmodic suspensions also contain relatively high amounts of suspended material for oral administration. The suspending vehicle can, for example, be a syrup, sorbitol solution, or gum-thickened water with added artificial sweeteners. Taste and viscosity are important considerations when formulating oral suspensions.

Many antibiotic drugs are unstable in the presence of an aqueous vehicle and, therefore, are frequently supplied as dry powder mixtures for reconstitution at the time of dispensing. Generally, this type of product is either a powder mixture or a completely granulated product, which upon dilution and agitation with a specified quantity of vehicle (e.g., water) results in the formation of a suspension suitable for administration. The preparation is typically designated in the USP by a title of the form "Dry Oral Suspension", whereas the ready-to-use suspension preparations are simply designated as "Oral Suspension". The dry mix products often contain drugs, colorants, flavorants, sweeteners (e.g., sucrose or sodium saccharin), stabilizing agents (e.g., citric acid, sodium citrate), suspending agents (e.g., guar gum, xanthan gum, methylcellulose), and preservatives (e.g., parabens, sodium benzoate).

The formulation of oral sustained-release suspensions has resulted in only limited success due to the difficulty in maintaining the stability of microencapsulated particles when present in liquid systems. Formulation techniques, such as oil-in-water emulsions, microencapsulation, and ion-exchange resins, have been used for this purpose (19-21). The combination of an ion-exchange resin complex with polyethylene glycol (PEG) followed by coating with a semipermeable polymer, such as ethyl cellulose (EC), in liquid suspensions (the dispersion medium being free of ions that could replace drug ions in the resin complex), the drug remains absorbed to the resin. However, upon swallowing ions from the gastrointestinal liquid can penetrate the particles and replace the drug ions, which subsequently diffuse out of the system (at a controlled, slow rate). Drug release from these systems depends on the type of drug-resin complex, on the ionic environment (e.g., pH and electrolyte concentration within the GI tract), as well as on properties of the resin. Most ion-exchange resins currently employed in sustained-release products contain sulfonic acid groups that exchange cationic drugs possessing anionic functionality. An example is hydroxystyrene sulfonate (Dowex® Polystyrene Sulfonate Resin, Sephadex®).

Topical suspensions are intended to be applied externally. Shale lotion and calamine lotion are good examples of historical products in this class. Because safety and toxicity are dealt with in terms of dermatological acceptability, many shale lotion suspending agents have been formulated for topical formulation. The preservative action and emulsifier properties of topical lotions usually require the use of high concentrations of disperse phase.
